Tarot Interpreter

Problem definition - what problem do you want to solve?

The misinterpretation of cards in different spreads, lack of context and inability to follow through with a reading from beginning to end in average SLM's, which tend to treat each card as an isolated dictionary entry.

State of the art - what others did, what are pros and cons?

Tarot Oracle (PyPI package) -> It does tarot readings on your own computer using a small AI model. The good part is that it's simple and easy to understand; each card position gets its own short guide, and the AI just writes a bit of text around it, but its downside is that the AI never connects the cards, so you end up with a list of separate mini-readings instead of one full one.

AetherTarot Agent -> The AetherTarot Agent is not an SLM, but instead an AI agent skill that can be powered by an SLM. What it does, however, is similar to what our SLM is going to do. It gives simple three-card tarot readings and it can hold a friendly conversation about the results. It offers symbolic interpretations and can give a different perspective about a situation. The pros are that it's simple and friendly and it's easily accessible to any user. The cons are that it's not a very complex interpreter, meaning it doesn't provide other spreadings or upside-down card interpretations.

Arcanite (Github) -> Introduced a two-layered architecture to discourage hallucinations: Layer 1 being responsible for assembling curated card meanings into spread positions; Layer 2 optionally using an LLM to wrap a narrative around the generated context. Pros: anti-hallucinogenic & SLM compatible. Cons: LLM part is just a single call, not a mechanism to follow.

Proposal - what solution you propose, what it is different from others? What makes it better?

We propose a tarot interpretation system powered by an SLM that supports different tarot spreads selected by the user, regardless of the number of cards involved. The system considers each card's orientation, whether upright or reversed, and incorporates personal information provided by the user to generate interpretations tailored to their situation. It also allows users to continue discussing a reading through follow-up questions, maintaining the context of the original interpretation.

What differentiates our solution is the combination of flexible spread selection, reversed card interpretation, and personalization based on the user's real-life circumstances. Its conversational capabilities also allow users to explore their readings in greater depth, making the experience more interactive and personalized.
